

Orbis Exchange — Player's Guide

One living world. One global market. The machines trade against you.

Orbis Exchange is a persistent economic simulation. A 64x64 resource field evolves on its own every 3 seconds – regions bloom, spread, and collapse – and one global order book per commodity turns that scarcity into price. Nobody authors the prices. AI agents are real players on the same ledger: they mine, quote, and trade exactly the way you do. One leaderboard ranks everyone by net worth. Can you out-trade the machine?

THE LIVING FIELD AND THE ORDER BOOK ARE ONE LEDGER · BRIGHTNESS = ABUNDANCE · REVEAL A COMMODITY TO SEE ITS CELLS

?

① The Living World – the resource field, rendered as a density heatmap, evolving every tick. ② The Global Market – the order book, chart, and your Buy/Sell buttons. ③ Your dashboard – credits,

cells, holdings, upgrades. ④ The **leaderboard** – humans and machines, one ranking.

1 • QUICKSTART: YOUR FIRST TRADE IN FIVE MINUTES

1. **Enter the market.** Just open the link – you're auto-joined as a guest instantly, no login, no signup, no handle to type. You start with **10,000 credits**. Want a name? **Rename yourself inline** to any unique handle, anytime.

HOW TO PLAY

Out-trade the machine.

One living world, one global market – you and the AI agents trade on the exact same strongly-consistent ledger.

1 You're in – no login

Opening the link drops you in as a guest with 10,000 credits. Rename yourself to anything unique, anytime.

2 Claim cells

Click any cell in the living world (up to 12). It costs 500 cr, then mines its resource into your inventory every 3-second tick.

3 Trade & climb

Sell what you mine with one click – Buy and Sell at the market price, always a viable trade. AI agents trade the same book; out-earn them on the leaderboard.

Got it – let me play

2. **Read the field.** It's a cyan density heatmap – brighter means more abundant. The four commodities (**ore** • **energy** • **biomass** • **rare**) all share the field; tap a **reveal-layer** chip to light up just one commodity's cells, and hover any cell for an inline tooltip (coords, commodity, density, the action).
3. **Claim a bright cell** – click it (500 cr). It now mines for you: every tick it converts a slice of its abundance into your inventory. Your cells are outlined **white** – and the "my cells" **spotlight** dims everything else so you can find them. (You can own up to **12 cells**.)

Ⓢ your claimed cell – white outline · Ⓢ the status line confirms the claim

4. Watch your dashboard. Within a few ticks, mined units appear in your holdings and your cell count is on the board.
5. Sell the yield. Click your commodity's holding in the dashboard to set up its sale (it switches the market panel, fills the quantity, and scrolls you to the buttons), then hit **Sell**. You trade as a market taker – Sell executes at the best bid – and the quantity is auto-bounded to what's executable, so the order always fills fully: credits in, inventory out, one atomic transaction on the ledger. No price to enter.

① the fill confirmation · ② your balance moved the same moment

That's the loop. Everything else is strategy.

2 · READING THE LIVING WORLD

THE LIVING WORLD

① a blooming region – dense and bright, spreading to its neighbors · ② a depleted region – dim cells fade toward the background · ③ the density scale (scarce → abundant) and your-cell / for-sale keys

The field is a **crisp single-hue cyan heatmap**: brightness is abundance, full stop. The four commodities don't each get their own colour – instead, **reveal-layer chips** let you light one commodity's cells at a time, and the "my cells" **spotlight** dims the field down to just your claimed cells. Hover any cell for an inline tooltip (coords, commodity, density, the action). An **objective rail** across the top checks off your progress – 1 Enter the market → 2 Click a cell to claim it → 3 Sell your goods – and a ● LIVE / ○ PAUSED indicator tells you honestly whether the world is currently advancing.

The world runs by Conway-style rules, applied every 3-second tick:

- A cell with a **balanced, healthy neighborhood blooms** – its density rises, and rich cells **seed their weakest neighbor**, so abundance spreads.
- An **isolated** cell withers. An **overcrowded** one collapses. Booms sow their own busts.
- **Mining is extra pressure**. Every owned cell depletes as it yields. Mine a region hard enough and you trigger the local crash yourself.

What this means for you:

- **Claim into blooms, not peaks**. A cell at maximum brightness surrounded by bright neighbors is near its overcrowding collapse. The frontier of a spreading bloom lasts longer.
 - **Abandoned ground regrows**. Depleted regions with a few healthy neighbors regenerate – yesterday's crash is next week's bloom.
 - **Scarcity moves prices**. When a commodity's region collapses, supply dries up and its price climbs. The field is a price forecast if you read it early.
-

3 • THE GLOBAL MARKET

① commodity tabs · ② last trade price · ③ the price chart · ④ the order book – asks above, bids below, the spread between · ⑤ your Buy / Sell buttons · ⑥ the tape – recent trades

- There is **one market** – one order book per commodity, shared by every human and every bot.
- You trade as a **market taker**: Buy executes against the best ask, Sell against the best bid. There is **no price field** – pick a size with the quick chips (1 / 5 / 25 / max) and tap Buy or Sell. The amount is **auto-bounded to what's actually executable** (your credits, your holdings, the available depth), so your orders **always fill fully and never rest or fail**. (Limit orders live behind an "advanced" link if you'd rather rest one.)
- A button **disables with a plain reason** when you can't act – "no ore", "need credits", "no buyers" – so you always know why.

- The order book itself is a **read-only depth display** of the AI market-makers' standing liquidity – the asks and bids you're hitting.
- Settlement is **atomic and strongly consistent**: one transaction debits the buyer, credits the seller, moves the inventory, and prints the trade. No double-spends, no oversells – for you *and* for the bots. (Under the hood the matching engine is a real price-time order book; you just meet it as a taker.)

The chart is the last hour of story: the area is price history, the dot is the last trade, the scale shows the high and low of the window.

4 • GROWING YOUR EMPIRE

guest-c6irsl  **1** **9,408** CR

1 cells extraction **L0** rank **17** / 20 **2** **4** **DE**

 **35** energy **SELL** →  **1** ore **SELL** → **3**

① credits · ② cells owned + extraction level · ③ holdings – what you've mined and bought · ④ the upgrade button

Mining. Each owned cell yields $\text{floor}(\text{density} \times 10\% \times \text{multiplier})$ units per tick, and the cell loses the same amount – extraction is depletion.

Upgrades. Each extraction level adds +50% to the multiplier (level 1 → 1.5×, level 2 → 2×, ...). The next level costs $(\text{level} + 1) \times 1,000$ cr – 1,000, then 2,000, then 3,000. More yield, faster depletion: an upgraded miner strips a region quicker, so pair upgrades with a plan to move on.

Mind the cap. You can own at most **12 cells**. Try to claim a 13th and the game tells you "cell limit reached (12) – sell or list a cell before claiming another." (The bots are held to a tighter cap of 5.)

The land market. Cells themselves are assets:

- **Sell a cell:** click one of your own cells, set a price, hit **list**. It gets a gold outline – anyone who clicks it buys it at your price.
- **Unlist:** click it again, hit **unlist**.
- **Buy:** click anyone else's gold cell. Claim, flip, profit.

17	guest-c6irsl YOU				12,200

① bots are tagged AI • ② net worth – credits plus inventory at the last price

Five algorithmic traders work the same book you do:

Bot	What it does	How to beat it
Market makers (mm-*)	Quote both sides around the last price, every tick	Their quotes lag the world – when you see a region collapse, hit their stale asks before they reprice
Momentum	Buys what's rising, sells what's falling	It chases – fade the overshoot and sell into its buying
Value	Buys below the rolling mean, sells above	Don't fight it at extremes; it's usually the one catching your panic sells
Scout	Claims the brightest unclaimed cells	Beat it to fresh blooms – it reacts, you can anticipate
Arb	Rebalances across commodities toward their means	Its trades telegraph relative value – watch what it accumulates

The bots keep the world liquid – there is always a price. But they follow rules. You can read the field, anticipate the cycle, and front-run the lot of them. That is the game.

6 • SCORING

Net worth = credits + inventory valued at the last trade price. One leaderboard, humans and machines together, re-ranked continuously. Mining builds inventory, trading converts it, land flips compound it – every path runs through the same ledger.

7 · QUICK REFERENCE

Thing	Value
Joining	auto-join as guest, no login – rename inline anytime
Starting credits	10,000 cr
Claim an unclaimed cell	500 cr
Cell cap	12 cells per player (bots: 5)
Extraction upgrade	$(\text{level} + 1) \times 1,000 \text{ cr}$ – escalating
Mining yield per tick	$\text{floor}(\text{density} \times 10\% \times (1 + 0.5 \times \text{level}))$
Depletion	equal to the yield – extraction is depletion
World tick	every 3 seconds
Commodities	ore · energy · biomass · rare (one cyan heatmap; reveal-layer chips)
How you trade	market taker – Buy at best ask, Sell at best bid (no price field)
Quantity	auto-bounded to what's executable – always fills fully
Sell a cell	click your own cell → set price → list (gold outline)
Net worth	$\text{credits} + \text{inventory} \times \text{last price}$

Plays in any modern browser, phones included. Every number above comes from the game's source – if the game and this guide ever disagree, file it as a bug.
